Amendment No. 1 May 1984
To
(First Revision)
Alterations
(Page 10, clause 5.2.2, last sentence)
Substitute the following for the existing sentence:

'In computing the value, any individual value more than 50 percent of the average calculated shall be neglected and average re-calculated (the values for all loose seams shall however be included).'

(Page 13, clause 5.3.3): 

a) Line 3 - Substitute 'around' for 'usually'

b) Line 6 - Add the words 'with the assumption of cylindrical failure surface' after 'obtained'

(Page 13, Fig. 3) - Substitute 'c_2/c_1' for 'c_1/c_2'.

(Page 14, Fig. 4, caption) - Substitute the following for the existing caption:

'Decreasing Cohesion with Depth in Case of Desiccated Cohesive Soil'

(Page 14, Table 4 and clause 5.3.3) - Substitute

\[
\frac{4 \lambda B}{q_d} \quad \text{for} \quad \frac{8 \lambda B}{q_d}
\]
(Page 15, clause 6.1.1, line 3) - Add the words 'from standard penetration resistance' after 'pressure'.

(Page 15, clause 6.1.1) - Add the following sentence in the end:

'This safe bearing pressure can also be calculated based on plate load test (see IS:1888-1982).'

(Page 15, foot-note with † mark) - Add the words 'of settlement' after 'calculation'.

(Page 15, foot-note) - Add the following additional foot-note:

'†Method of load test on soils (second revision)'.

(BDC 43)
Indian Standard

CODE OF PRACTICE FOR
DETERMINATION OF BREAKING CAPACITY
OF SHALLOW FOUNDATIONS

( First Revision )

0. FOREWORD

0.1 This Indian Standard (First Revision) was adopted by the Indian Standards Institution on 30 January 1981, after the draft finalized by the Foundation Engineering Sectional Committee had been approved by the Civil Engineering Division Council.

0.2 The bearing capacity of foundations is needed for dimensioning the foundation for any structure. Several methods are available for the determination of bearing capacity of shallow foundations and this standard gives some of the methods which are commonly used for the purpose. Comparison of the results shows that when each of the various methods is applied to different problems no one method consistently gives higher or lower values of allowable bearing pressure. The designer must therefore regard the methods as aids to design which cannot replace the critical role of engineering judgement.

0.2.1 This standard was first published in 1971. The principal modifications made in this revision are: (a) keeping its terminology in line with that of other related Indian Standards, (b) giving generalized equations for calculation of ultimate bearing capacity, (c) including cone penetration methods and (d) deleting adjustment for fine sand and silt.

0.3 For the purpose of deciding whether a particular requirement of this standard is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS: 2-1960*. The number of significant places retained in the rounded off value should be the same as that of the specified value in this standard.

*Rules for rounding off numerical values (revised).
1. SCOPE

1.1 This standard covers the procedure for determining the ultimate bearing capacity and allowable bearing pressure of shallow foundations based on shear and allowable settlement criteria.

2. TERMINOLOGY

2.0 For the purpose of this standard, the following definitions shall apply.

2.1 Terms Relating to Bearing Capacity

2.1.1 Net Loading Intensity — The net loading intensity on the foundation is the gross intensity of loading minus the weight of displaced soil above the foundation base.

2.1.2 Ultimate Bearing Capacity — The intensity of loading at the base of the foundation which would cause shear failure of the soil support.

2.1.3 Safe Bearing Capacity — Maximum intensity of loading that the foundation will safely carry without the risk of shear failure of soil irrespective of any settlement that may occur.

2.1.4 Safe Bearing Pressure or Net Soil Pressure for Specified Settlement — The intensity of loading that will cause a permissible settlement or specified settlement of the structure.

2.1.5 Allowable Bearing Capacity — The net intensity of loading which the foundation will carry without undergoing settlement in excess of the permissible value for the structure under consideration but not exceeding net safe bearing capacity.

2.2 General Terms

2.2.1 Density Index (Relative Density) — The ratio of the difference between the void ratios of cohesionless soil in the loosest state and any given state to the difference between its void ratios at the loosest and densest states.

2.2.2 Effective Surcharge at the Base Level of Foundation — The intensity of vertical pressure at the base level of foundation, computed assuming total unit weight for the portion of soil above the water table and submerged unit weight for the portion below the water table.

2.2.3 Footing — A structure constructed in brickwork, masonry or concrete under the base of a wall or column for the purpose of distributing the load over a larger area.

2.2.4 Foundation — That part of a structure which is in direct contact with soil and transmits loads into it.
2.2.5 Shallow Foundation — A foundation whose width is greater than its depth. The shearing resistance of the soil in the sides of the foundation is generally neglected.

3. SYMBOLS

3.1 For the purpose of this code and unless otherwise defined in the text, the following letter symbols shall have the meaning indicated against each:

- \( A \) = Area of footing in cm²
- \( A' \) = Effective area of footing in cm²
- \( B \) = Width of strip footing, width of footing, side of square footing, diameter of circular footing in cm
- \( B' \) = Effective width of footing in cm
- \( b \) = Half of \( B \)
- \( c \) = Cohesion in kgf/cm²
- \( c_1 \) = Undrained cohesion of the top layer in kgf/cm²
- \( c_2 \) = Undrained cohesion of the lower clay layer in kgf/cm²
- \( D_f \) = Depth of foundation in cm
- \( D_w \) = Depth to water table in cm
- \( d \) = Depth of top clay layer with undrained cohesion \( c_1 \)
- \( d_q, d_s, d_f \) = Depth factors
- \( e \) = Eccentricity of loading in cm
- \( e_n \) = Eccentricity of loading along the width in cm
- \( e_L \) = Eccentricity of loading along the length in cm
- \( H \) = Horizontal component of loading in kgf
- \( i_q, i_q, i_f \) = Inclination factors
- \( K_d \) = Depth factor (varies linearly from 1 for depth \( D_f = 0 \) to 1.33 for depth \( D_f = B \))
- \( L \) = Length of footing in cm
- \( L' \) = Effective length of footing in cm
- \( N \) = Corrected standard penetration value
- \( N_0, N_e, N_s, N_0, N_L, N_f \) = Bearing capacity factors
\[
N\phi = \tan^2 (\pi/4 + \phi/2)
\]

\( q \) = Effective surcharge at the base level of foundation in kgf/cm²

\( q_a \) = Net soil pressure for a specified settlement of 25 mm in kgf/cm²

\( q_o \) = Static cone penetration resistance in kgf/cm²

\( q_a' \) = Net ultimate bearing capacity based on general shear failure in kgf/cm²

\( q_a'' \) = Net ultimate bearing capacity based on local shear failure in kgf/cm²

\( R \) = Relative density of soil

\( W' \) = Correction factor for location of water table

\( s_h, s_q, s_f \) = Shape factors

\( \alpha \) = Inclination of the load to the vertical in degrees

\( \phi \) = Angle of shearing resistance of soil in degrees

\( \gamma \) = Bulk unit weight of foundation soil kgf/cm³

4. GENERAL

4.1 Sufficient number of undisturbed samples, about 40 to 100 mm in diameter or more or block samples should be obtained, where possible. These samples are for the determination of field density of soil and conducting tests for determining the relevant shear and consolidation parameters of the soil. Tests on soils should be conducted in accordance with relevant parts of IS : 2720*.

4.2 Position and fluctuation of water table should be ascertained. Reference may be made to IS : 1892-1979† and IS : 2132-1972‡ for guidance regarding investigations and collection of data.

5. ULTIMATE NET BEARING CAPACITY

5.0 General — Three types of failure of soil support beneath the foundations have been recognized, depending upon the deformations associated with the load and the extent of development of failure surface.

---

*Method of test for soils.
†Code of practice for subsurface investigations for foundations (first revision).
‡Code of practice for thin-walled tube sampling of soils (first revision).
They are: a) general shear failure, b) local shear failure and c) punching shear. The choice of which method of analysis is best suited in a given situation is difficult to make, because only limited test data are available on full sized foundations to verify the reliability of the computed bearing capacity. However, guidelines given in relevant clauses may be used for guidance. Wherever possible bearing capacity calculations shall be made on the basis of shear strength parameters $\phi$ and $c$ obtained from appropriate shear tests [see IS : 2720 (Parts XI and XIII)*] or from plate load test results as given in IS : 1888-1981† or from static cone penetration resistance $q_0$ obtained from static cone penetration test as given in IS : 4968 (Part III)-1976‡.

5.0.1 Effect of Eccentricity

a) Single Eccentricity — If the load has an eccentricity $e$, with respect to the centroid of the foundation in only one direction, then the dimension of the footing in the direction of eccentricity shall be reduced by a length equal to $2e$. The modified dimension shall be used in the bearing capacity equation and in determining the effective area of the footing in resisting the load.

b) Double Eccentricity — If the load has double eccentricity ($e_L$ and $e_R$) with respect to the centroid of the footing then the effective dimensions of the footing to be used in determining the bearing capacity as well as in computing the effective area of the footing in resisting the load shall be determined as given below:

$$L' = L - 2e_L$$
$$B' = B - 2e_R$$
$$A' = L' \times B'$$

5.1 Soils with Cohesion and Angle of Shearing Resistance

5.1.1 The following formulae shall be used for calculating ultimate net bearing capacity in the case of strip footings:

a) In case of general shear failure $q_a = cN' + q (N_q - 1) + \frac{1}{2} B Y N_{\gamma}$

b) In case of local shear failure $q'_a = \frac{1}{2} cN'_e + q (N'_q - 1) + \frac{1}{2} B Y N'_{\gamma}$

The values of $N_e, N'_e, N_q, N'_q, N_{\gamma}$ and $N'_{\gamma}$ may be obtained from Table 1.

*Methods of test for soils: Part XI Determination of shear strength parameters of a specimen tested in unconsolidated undrained triaxial compression without the measurement of pore water pressure, and Part XIII Direct shear test (first revision).

†Method of load test on soils (second revision).

‡Method for subsurface sounding for soils: Part III Static cone penetration test (first revision).
TABLE 1 BEARING CAPACITY FACTORS

(Clause 5.1.1)

Note — For obtaining values of N₀, Nₗ, and N'γ, calculate φ' = tan⁻¹ (0.67 tan φ). Read N₀, Nₗ, and N'γ from the Table corresponding to the value of φ' instead of φ which are values of N₀, Nₗ, N'γ respectively.

5.1.2 The ultimate net bearing capacity obtained in 5.1.1 for strip footing shall be modified to take into account, the shape of the footing, inclination of loading, depth of embedment and effect of water table. The modified bearing capacity formulae are given as under:

a) In case of general shear failure qₐ

\[ qₐ = cN₀ \sigma_{cd}σ_{e0} + q(Nₗ - 1)\sigma_d\sigma_i \frac{1}{B^2 N'γ} \gamma W' \]

b) In case of local shear failure q'd

\[ q'd = cN'₀ \sigma_{cd}σ_{e0} + q(N'ₗ - 1)\sigma_d\sigma_i \frac{1}{B'N'γ} \gamma W' \]

5.1.2.1 The shape factors shall be as given in Table 2.

TABLE 2 SHAPE FACTORS

<table>

<td>1.3</td>
<td>1.2</td>
</tr>
</tbody>
</table>

Use B as the diameter in the bearing capacity formula.
5.1.2.2 The depth factors shall be as under:

\[ d_0 = 1 + 0.2 \frac{D_t}{B} \sqrt{\alpha} \]
\[ d_q = \gamma = 1 \text{ for } \phi < 10^\circ \]
\[ d_q = \gamma = 1 + 0.1 \frac{D_t}{B} \sqrt{\alpha} \text{ for } \phi > 10^\circ \]

Note — The correction is to be applied only when back filling is done with proper compaction.

5.1.2.3 The inclination factor shall be as under:

\[ i_e = i_q = \left(1 - \frac{\alpha}{90}\right)^2 \]
\[ i_\gamma = \left(1 - \frac{\alpha}{\phi}\right)^2 \]

5.1.2.4 Effect of water table

a) If the water table is likely to permanently remain at or below a depth of \((D_t + B)\) beneath the ground level surrounding the footing then \(W'' = 1\).

b) If the water table is located at a depth \(D_t\) or likely to rise to the base of the footing or above then the value of \(W''\) shall be taken as 0.5.

c) If the water table is likely to permanently got located at depth \(D_t < D_w < (D_t + B)\), then the value of \(W''\) be obtained by linear interpolation.

5.2 Cohesionless Soil \((c = 0)\) — The ultimate net bearing capacity shall be calculated as given in 5.2.1 and 5.2.2.

5.2.1 Based on Relative Density — The formulae given in 5.1.1 and 5.1.2 shall be used, together with relevant shear strength parameter.

5.2.1.1 The relative density as given in Table 3 shall be used as a guide to determine the method of analysis.

<table>

<td>Interpolate between i) and ii)</td>
</tr>
</tbody>
</table>
5.2.2 Based on Standard Penetration Resistance Value — The standard penetration resistance shall be determined as per IS : 2131-1981* at a number of selected points at intervals of 75 cm in the vertical direction or change of strata if it takes place earlier and the average value beneath each point shall be determined between the level of the base of the footing and the depth equal to 1.5 to 2 times the width of foundation. In computing the average any individual value more than 50 percent greater than the average shall be neglected, but the values for all loose seams shall be included.

5.2.2.1 The ultimate net bearing capacity shall be calculated from following formula (covering effect of other factors as mentioned in 5.1.2):

\[ q_a = q(N_q - 1) s_d q_i + \frac{1}{2} B Y N_s q d q_i W' \]

Where \( \phi \) may be read from Fig. 1, \( N_Y, N_q \) may be read from Table 1, \( S_d, q_i, q_r, d_q, i_q, W' \) may be obtained as in 5.1.

5.2.3 Method Based on Static Cone Penetration Test — The static cone point resistance \( q e \) shall be determined as per IS : 4968 (Part III)-1976† at number of selected points at intervals of 10 to 15 cm. The observed values shall be corrected for the dead weight of sounding rods. Then the average value at each one of the location shall be determined between the level of the base of the footing and the depth equal to \( 1 \frac{1}{2} \) to 2 times the width of the footing. The average of the static cone point resistance values shall be determined for each one of the location and minimum of the average values shall be used in the design. The ultimate bearing capacity of shallow strip footings on cohesionless soil deposits shall be determined from Fig. 2.

5.3 Cohesive Soil (when \( \phi = 0 \))

5.3.1 Homogeneous Layer

5.3.1.1 The net ultimate bearing capacity immediately after construction on fairly saturated homogeneous cohesive soils shall be calculated from following formula:

\[ q_a = cN_s s_c d_c i_c \]

where

\[ N_c = 5.14. \]

*Method for standard penetration test for soils (first revision).
†Method for subsurface sounding for soils: Part III Static cone penetration test (first revision).
Fig. 1 Relationship Between $\phi$ and $N$
The value of $c$ shall be obtained from unconfined compressive strength test. Alternatively, it can also be derived from static cone test (see 5.3.1.2). The values of $s_e$, $d_e$ and $i_e$ may be obtained as in 5.1. If the shear strength for a depth of $\frac{1}{4} B$ beneath the foundation does not depart from the average by more than 50 percent, the average may be used in the calculation.

5.3.1.2 Alternately, cohesion $c$ shall be determined from the static cone point resistance $q_e$ using the empirical relationship shown below:

<table>
<thead>
<tr>
<th>Soil Type</th>
<th>Point Resistance Values $(q_e)$ kgf/cm²</th>
<th>Range of Undrained Cohesion $(kgf/cm²)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normally consolidated clays</td>
<td>$q_e &lt; 20$</td>
<td>$q_e/18$ to $q_e/15$</td>
</tr>
<tr>
<td>Over consolidated clays</td>
<td>$q_e &gt; 20$</td>
<td>$\frac{q_e}{26}$ to $\frac{q_e}{22}$</td>
</tr>
</tbody>
</table>

5.3.2 Two Layered System — In the case of two layered cohesive soil system which do not exhibit marked anisotropy the ultimate net bearing capacity of a strip footing can be calculated by using the formula given below:

$$q_d = c_s N_c$$

where $N_c$ may be obtained from Fig. 3.
5.3.3 Desiccated Soil — In the case of desiccated cohesive soils, the undrained cohesion is likely to decrease along with depth and is likely to get stabilized at some depth below ground level, usually 3.5 m, if other factors do not influence. If a plot of undrained cohesion, values as shown in Fig. 4 is obtained, and where the pressure bulb falls within the desiccated top soil the ultimate net bearing capacity shall be obtained from Table 4.

![Diagram of layered cohesive soil deposits]

</tbody>
</table>

\( \lambda, c_1 \) shall be obtained from the borehole data, and for a known value of the width of the strip footing ‘B’, by trial and error \( q_d \) can be estimated by matching \( \frac{8AB}{q_d} \) with \( \frac{qd}{c_1} \).

6. ALLOWABLE BEARING CAPACITY

6.1 The allowable bearing capacity shall be taken as either of the following, whichever is less:

a) Net ultimate bearing capacity as obtained in 5 divided by suitable factor of safety, that is, net safe bearing capacity.
b) The net soil pressure (see 6.1.1) that can be imposed on the base without the settlement exceeding the permissible values as given in IS: 1904-1978* to be determined for each structure and type of soil, that is, safe bearing pressure.

6.1.1 Safe Bearing Pressure — The permissible settlements for different types of soil formations are specified in IS: 1904-1978*. The methods for calculations of settlements for assumed pressure are specified in IS: 8009 (Part I)-1976†; by calculating the settlements for two or three probable soil pressures and interpolating, the net soil pressure for permissible settlement may be estimated.
